ABSTRACT:

A method of simultaneously executing one or more computer application programs in one or more host computer system or server system under the control of a second computer system, where the host computer system or server system generates either presentation information or generic computer messages, or both, based on the application programs, involves establishing selected parameters in the host computer presentation information or messages, or both, interpreting selected portions of the host computer system's presentation information or message information, or both, as input to a computer program resident in the second computer system, examining the host computer system presentation information or message information, or both, at the second computer system to detect the presence therein of one or more of the selected parameters utilizing information in a custom object database, and continuing operation of the second computer system during the examining for the selected parameters.

ABSTRACT:

A system, method and article of manufacture are provided for implementing communication services patterns. A fixed format stream-based communication system is provided and service is delivered via a globally addressable interface. Access is afforded to a legacy system. Service is delivered via a locally addressable interface. A null value is communicated and data is transmitted from a server to a client via pages. A naming service and a client are interfaced with the naming service allowing access to a plurality of different sets of services from a plurality of globally addressable interfaces. A stream-based communication system is provided and data is efficiently retrieved.

File: USPT

Apr 9, 2002

DOCUMENT-IDENTIFIER: US 6370455 B1

TITLE: Method and apparatus for networked wheel alignment communications and service

Brief Summary Paragraph Right (5):

Such a vehicle wheel alignment system further should provide improved Internet integration of the automotive diagnostic or wheel alignment system when compared to conventional automotive diagnostic or vehicle wheel alignment systems. For example, a vehicle wheel alignment system utilizing Internet integration should include an ability to utilize Microsoft's standard or compact versions of "dot"-NET (or NET) Web Services, which are building blocks for constructing distributed Internet or web-based applications in a platform, object model, and multi-language manner. These "dot"-NET Web Services are based upon open Internet standards and protocols, such as HTTP and XML, and provide a URL-addressable resource which programmatically returns information to systems who want to use it, without the systems needing to know how the service has been implemented. Specifically, Web Services represents black-box functionality which may be reused without concern for how the service is implemented, by providing well-defined user interfaces, known as "contracts," which describe the features of the service. In this manner, vehicle wheel alignment applications can be assembled from a variety of components, consisting of remote services accessed via the Internet, local services, and custom software written in an intermediate language, any of several computer languages including C#, Visual Basic, C++, Cobol, Perl, Java, JScript and VBScript, and may utilize component object model (COM) and distributed COM (DCOM) standards. Individual "dot"-NET Web Services and components can be further enhanced by using "inheritance" properties to extend the capabilities of existing components. These remote and local services and custom software may further utilize a standard "dot"-NET framework or information exchange protocol, such as Microsoft's Simple Object Access Protocol (SOAP) to exchange information over the Internet. The SOAP methodology provides a lightweight protocol for the exchange of information in a decentralized and distributed environment, such as the Internet. SOAP is an XML based protocol which consists of three parts, an envelope for defining a framework for the contents of a message and the manner in which it is to be processed, a set of encoding rules for expressing datatypes, and a convention for representing remote procedure calls and responses.

ART-UNIT: 3661

PRIMARY-EXAMINER: Beaulieu; Jonel

ATTY-AGENT-FIRM: Folster, Lieder, Woodruff & Lucchesi, LC

ABSTRACT:

A wheel alignment system including at least one sensing device for acquiring automotive data, interface circuitry in communication with the sensing device for generating data representative of automotive data acquired by the sensing device, and a host computer in communication with the interface circuitry for performing a sequence of operations on the data generated by the interface circuitry. The host computer provides integrated Internet access to allow for transmission to the vehicle wheel alignment system, from a remote server, via the Internet, updated information and software applications and components necessary to accurately diagnose a vehicle, and the return of diagnostic, statistical, and log information associated with the vehicle wheel alignment system. The host computer provides integrated Internet access to allow for transmission of electronic commerce and statistical information, alignment logs, error messages, status messages, or diagnostic information to a remote system, and for the receipt of information including updated software applications, diagnostic commands, and remote information queries therefrom.
